

Nuclear Medicine

- Unsealed radioactive preparations
the tracer mixes with the patients' body fluids on a molecular level (e.g. after intravenous injection)
- 3 main fields:
 - „In vitro”: measuring concentrations of different molecules
 - „In vivo” imaging
 - Therapy
- Functional imaging
while X-ray, US, MRI are structural

- Book: Nukleáris Medicina
(Szerk. Szilvási I., Medicina Kiadó, 2010)

2

Nuclear imaging

Problems to solve:

- To produce radionuclides
- To link them to carrier molecules: radiopharmaceuticals
- To image the distribution of the tracer

3

Gamma cameras

SPECT/SPET: „single photon emission computed tomography”

4

Radiopharmaceuticals: Examples

Binding ^{99m}Tc or some other radionuclide to a carrier molecule → different functions

<i>Radionuclide - radiopharmaceutical</i>	<i>Mechanism</i>	<i>Study type</i>
$^{99m}\text{TcO}_4^-$ (pertechnetate)	(Iodine) trapping	thyroid scintigraphy
$[^{99m}\text{Tc}] \text{MDP}$	osteoblasts	bone scintigraphy
$[^{99m}\text{Tc}] \text{MIBI}$	mitochondria	myocardial perfusion parathyroid scintigraphy breast scintigraphy
$[^{99m}\text{Tc}] \text{DMSA}$	proximal tubules	kidney scintigraphy
$[^{18}\text{F}] \text{FDG}$	glucose metab.	metabolic imaging
etc.		

4

Emission imaging: study types

Static:

Imaging an equilibrium distribution

Whole body:

Static images connected

Dynamic:

Series of images following the accumulation / metabolic pathways / secretion of a radiopharmaceutical

Tomographic:

Single photon emission computed tomography (**SPECT**)
positron emission tomography (**PET**)

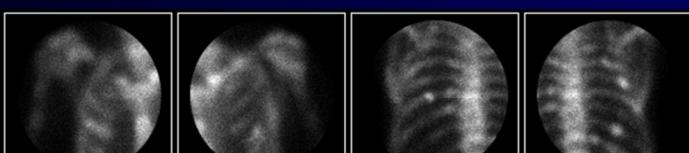

6

Bone scintigraphy - technique

<i>Pharmaceuticals:</i>	$[^{99m}\text{Tc}]$ diphosphonates (MDP, HEDP)
<i>Used mechanism:</i>	Osteoblastic activity + blood perfusion
<i>Time of scanning:</i>	2-3 hours post injection.
<i>Usual pictures</i>	1. Spot images 2. Whole body scan
<i>Quantitative data:</i>	Sacroiliac joint index
<i>Abnormality detected:</i>	High activity at tumor or metastatic sites, in osteomyelitis, etc.
<i>Not useful:</i>	in osteoporosis, at lytic bone sites

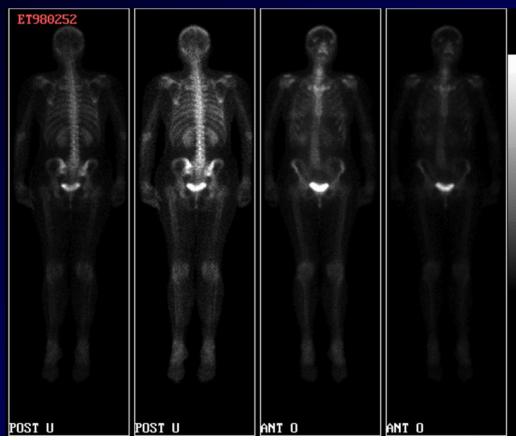

7

Bone scintigram (spot images)

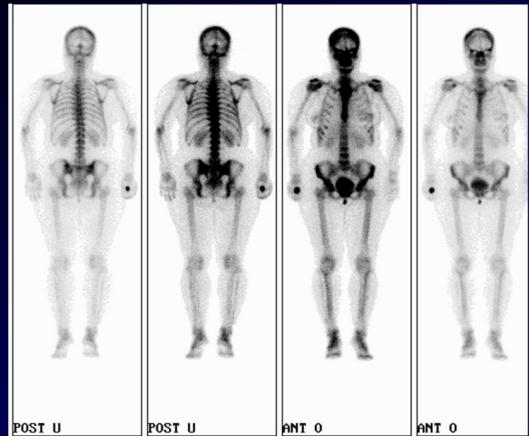

8

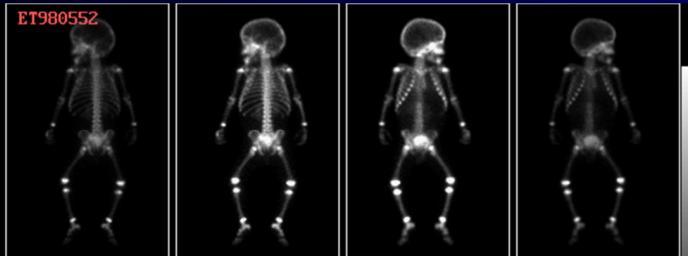

Normal whole body bone scintigram

Normal whole body

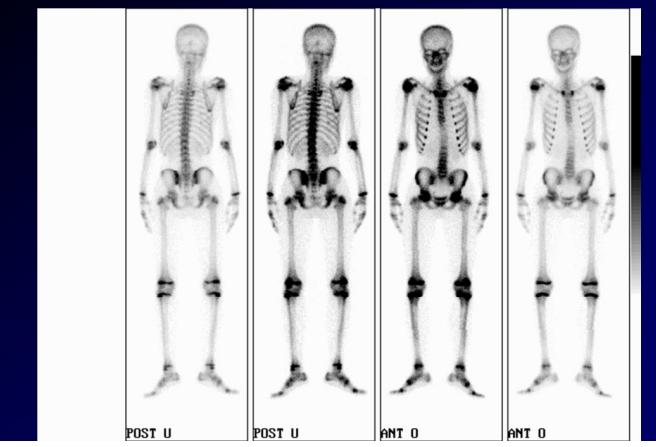

High osteoblast activity in the joints of an infant

11

Normal whole body (young patient)

Bone scintigraphy - indications

1. To detect and follow up **bone metastases** (mainly of breast, prostate or lung cancer)
2. **Benign illnesses:**
 - osteomyelitis
 - fractures
 - cause of joint prosthesis pain
 - aseptic necrosis of bones
 - osteodystrophy (renal origin)

13

1. Oncological indications:

- Secondary tumours (metastases)
 - Staging and follow-up of neoplastic diseases.
 - Distribution of osteoblastic activity prior to radiometabolic therapy (⁸⁹Sr, ¹⁵³Sm-EDTMP, ¹⁸⁶Re-HEDP).
- Primary tumours (e.g. Ewing's sarcoma, osteosarcoma).
 - Staging,
 - Evaluation of response to therapy and
 - Follow-up of primary bone tumors

14

2. Non-neoplastic diseases:

- Osteomyelitis
- Perthes Disease, Avascular necrosis
- Metabolic disorders (Paget, osteoporosis)
- Arthropathies
- Fibrous dysplasia and other rare congenital conditions
- Stress fractures, shin splints
- Loose or infected joint prosthesis
- Low back pain, sacroiliitis
- Reflex sympathetic syndrome
- Any other bone injuries

15

Factors influencing the uptake and distribution of radiopharmaceutical:

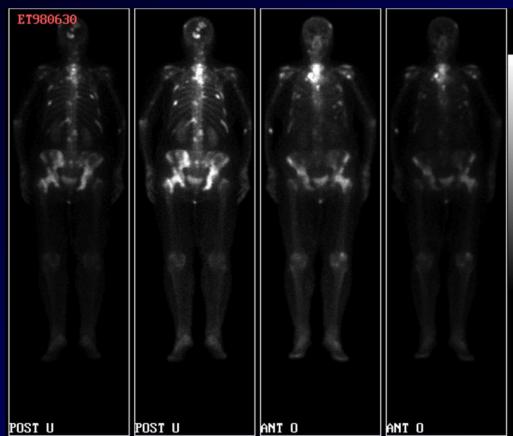

- Osteoblast activity
- Blood supply

False negative bone scintigram occurs:

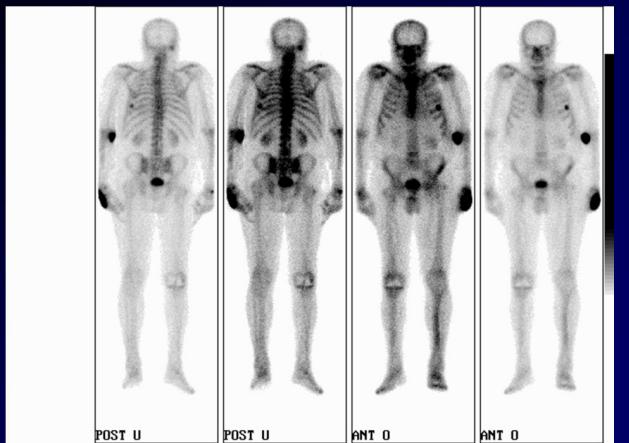

- Lower local blood perfusion
- Dominant osteoclast activity
- A process primarily involving the bone marrow
- Therapy with phosphonates

16

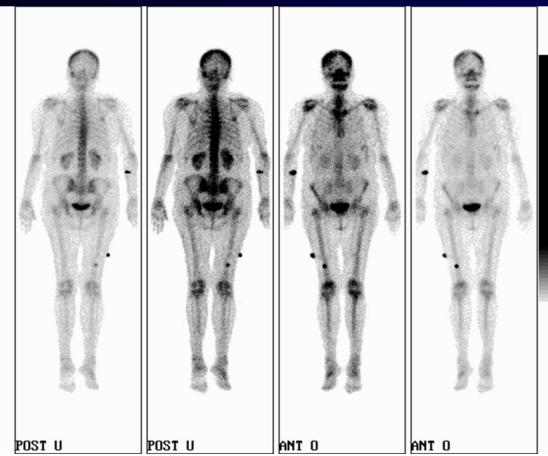

Multiple metastases

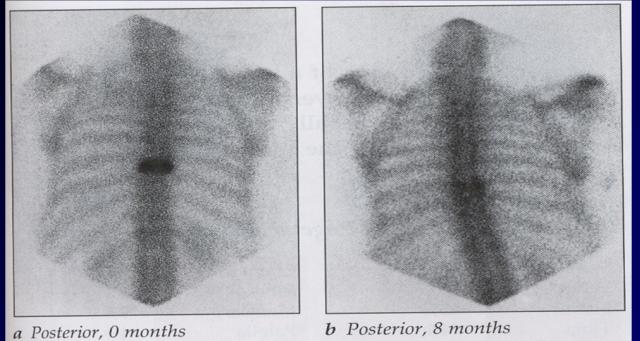

Rib and vertebra

Urinary contamination

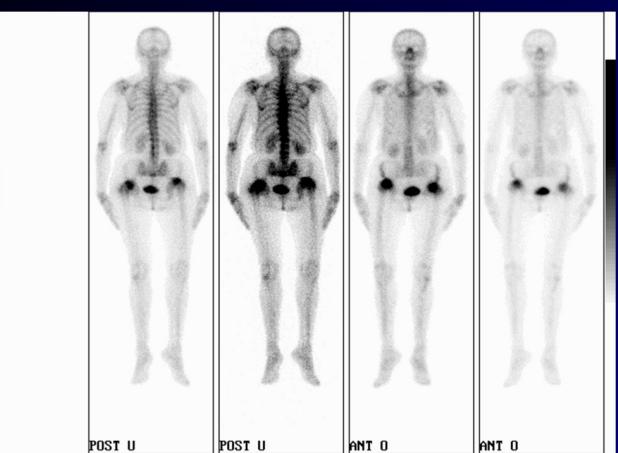

Osteoporotic collapse

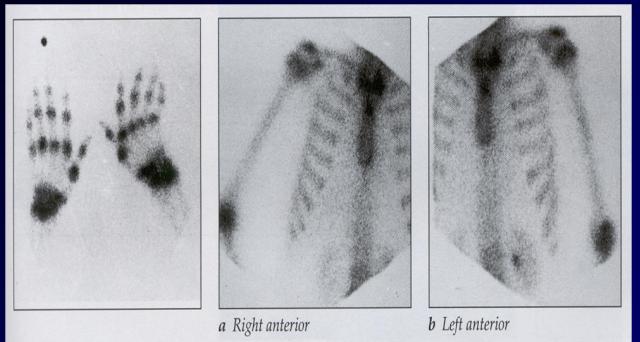

20

Degenerative disease affecting hips

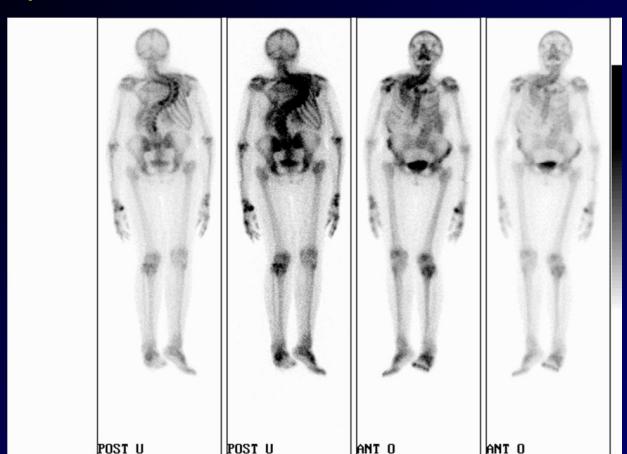

Rheumatoid arthritis

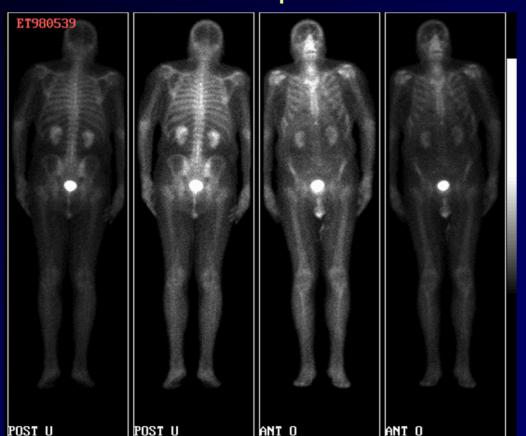

22

Spinal torsion

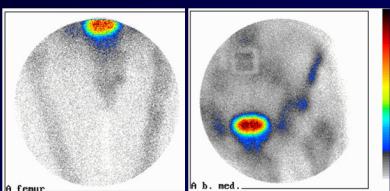

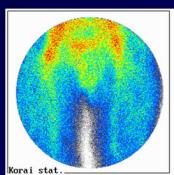

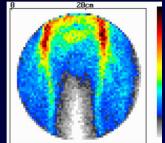

Scattered radiation in a fat patient

3-phase bone scintigraphy

3 phases:

- radioangiography
- early (blood pool)
- osteoblast activity

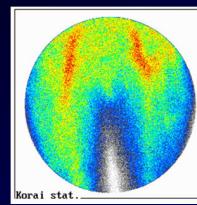

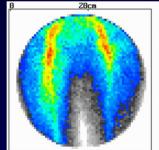

25

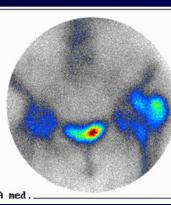

3-phase bone scintigraphy

painful prosthesis:
loosening

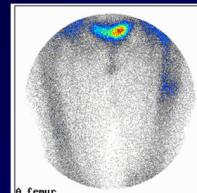

Sum of dynamic series

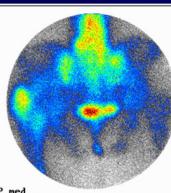

Early phase

Delayed

a femur

P med.

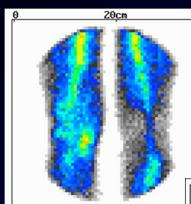

26

Differential diagnosis: painful prosthesis

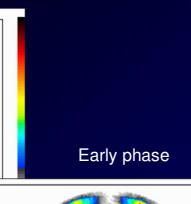

Prosthesis ...	Blood pool (early phase)	Late uptake
loosening	normal	increased
infection	increased vascularity	increased

27

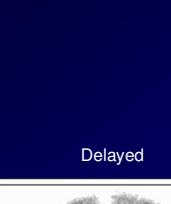

3-phase bone scintigraphy: Osteomyelitis

Sum of dynamic series

Early phase

Delayed

Korai stat. i.

Differential diagnosis: osteomyelitis

	Blood pool	Late uptake
Septic arthritis, cellulitis	increased	normal or low
Acute osteomyelitis	increased vascularity	increased

29

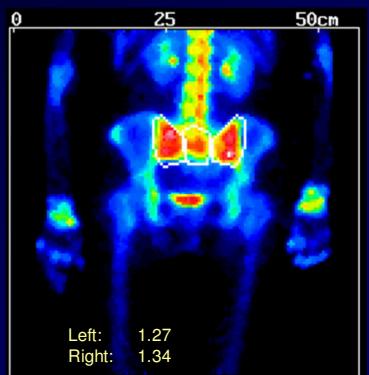

Quantitative parameters

SACROILIAC INDEX:

ROIs to sacral and sacroiliac region

$$SI - \text{index} = \frac{\text{maximum SI pixel (count)}}{\text{maximum S pixel (count)}}$$

normal value: < 1.65
if elevated \rightarrow sacroiliitis

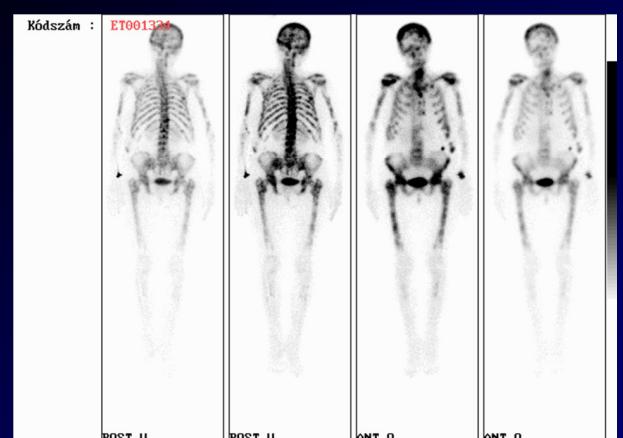

30

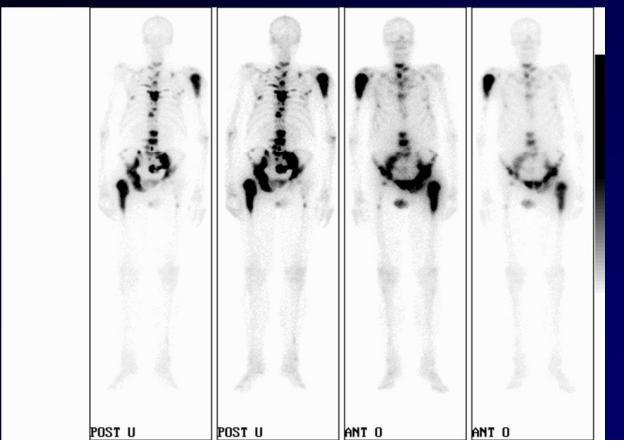

Examples

31

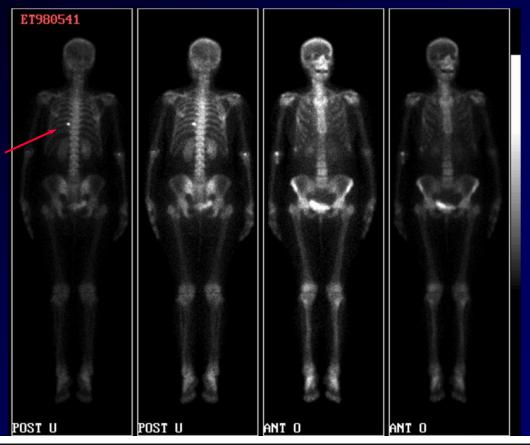

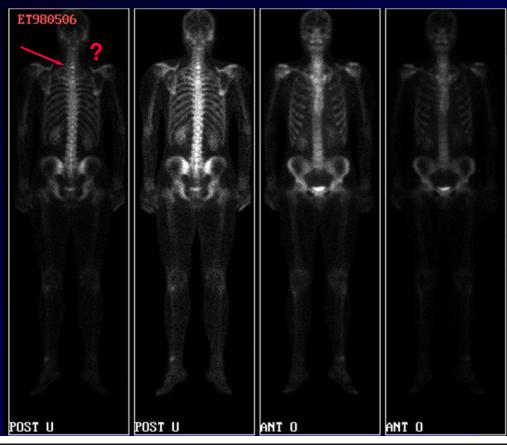

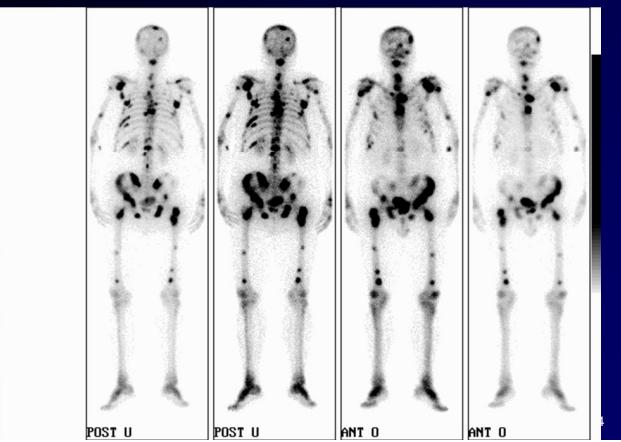

Multiple metastases

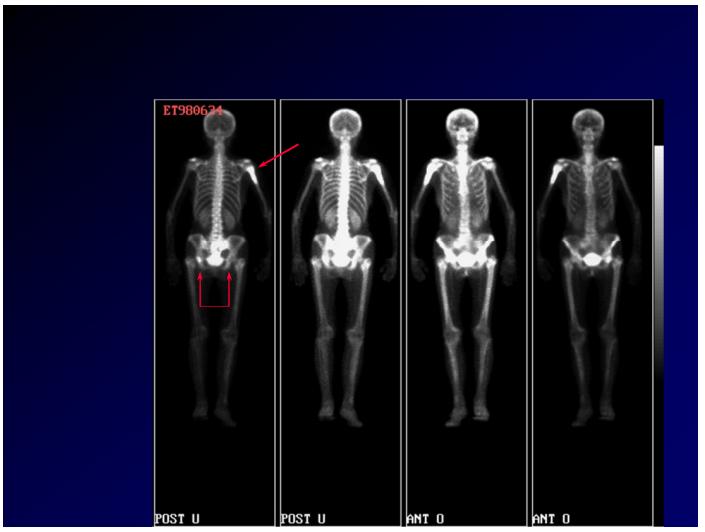

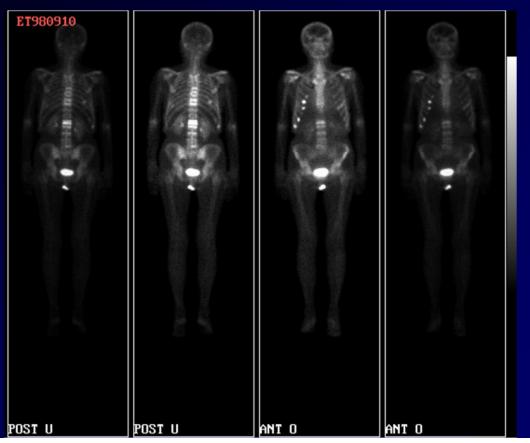

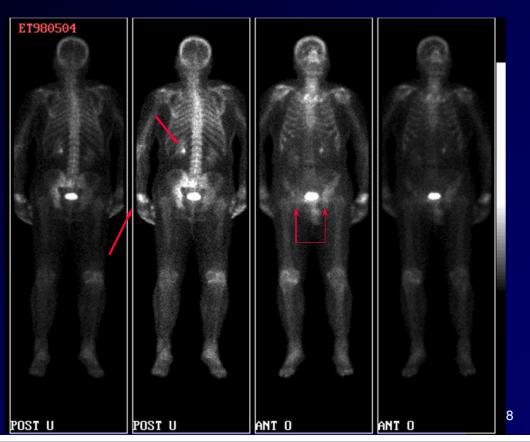

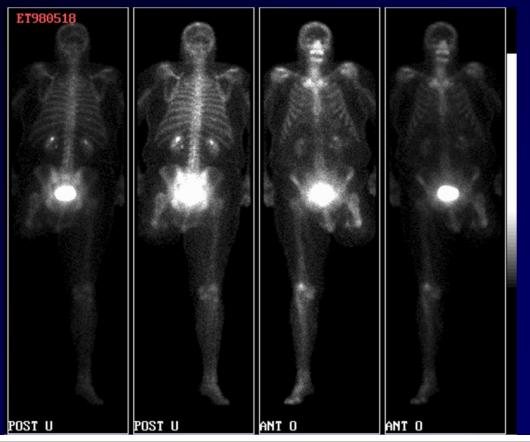

Multiple metastases

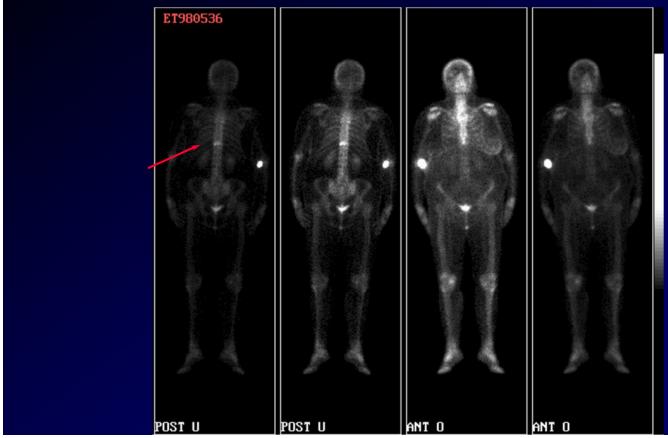

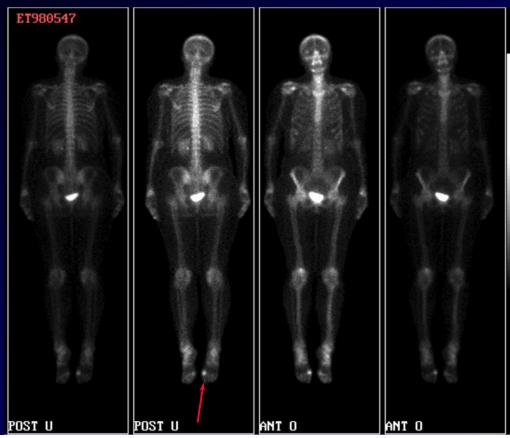

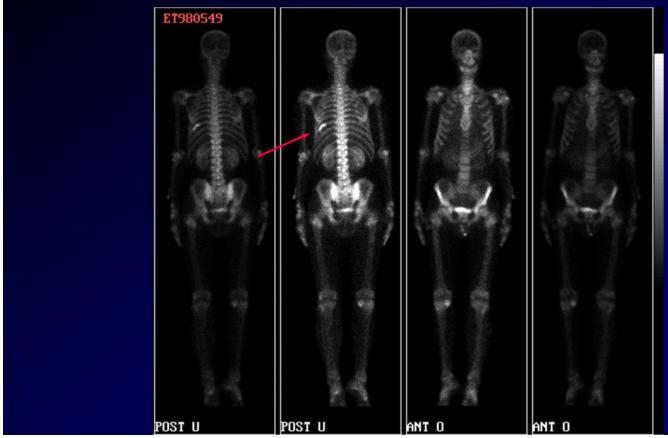

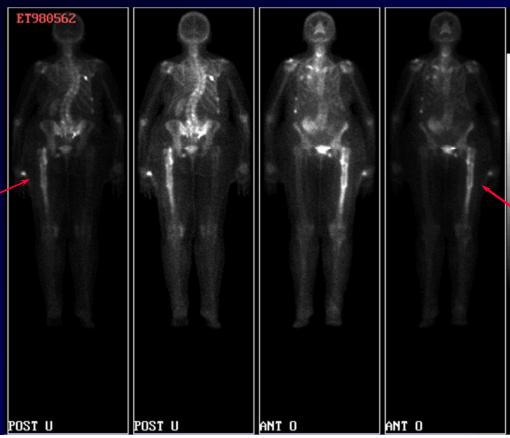

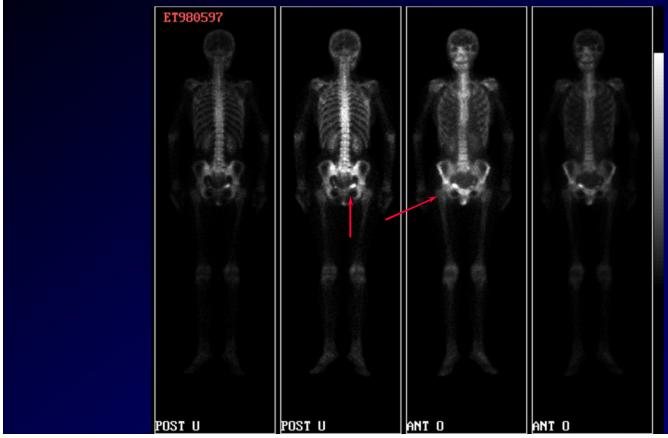

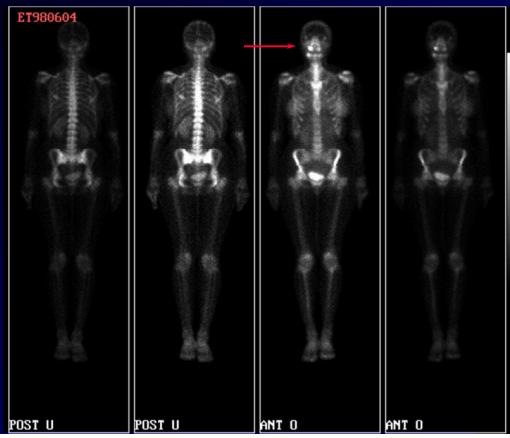

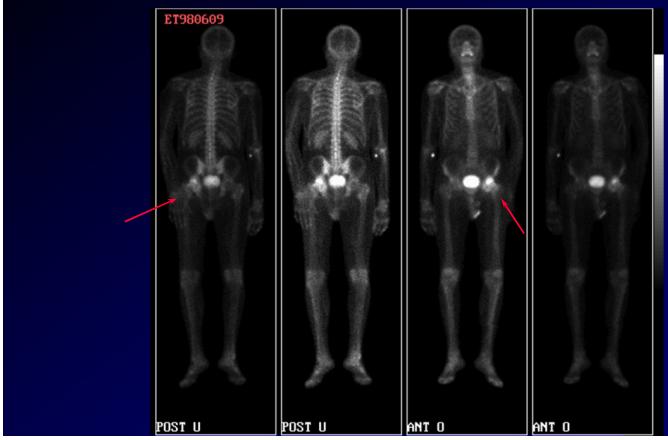

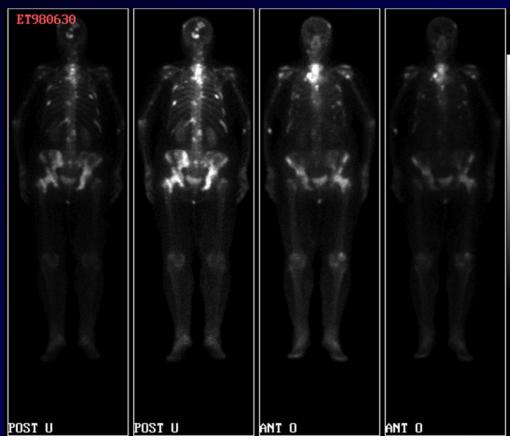

Multiple metastases

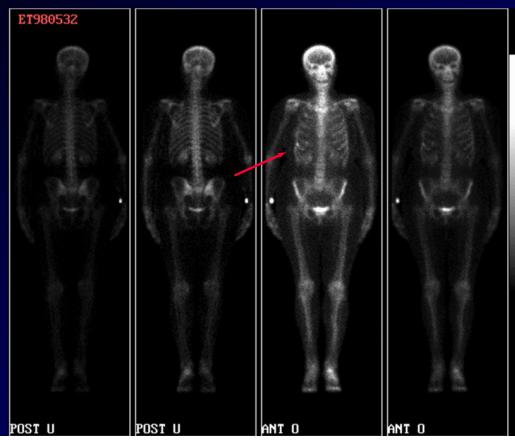

Huge bladder (patient could not void)

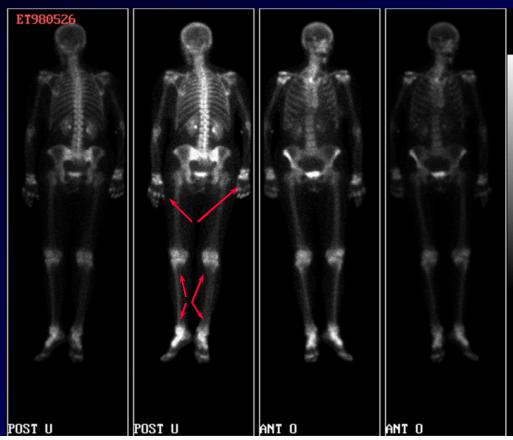

Metast.: rib

Increased uptake in inflammatory joints

Metastases in ribs
